Hypothesis – Agent-Based Modeling of Pandemic Spread

(i.) At high mobility, agents are likely to "blend well", creating a long-lasting high outbreak peak. Hence, I assume that the peak will be lowered and less steep when movements are reduced.

(ii) I suppose there should be several patterns based on initial settings: If the infected are rather clustered initially and becoming well soon, the outbreak may just vanishes; if they are spread-out and contacted many susceptible, there might be a long outbreak.

(iii). Since we are not assuming recovered agents will be infected again, we shouldn't see multiple rounds of outbreaks as the in-class simulation.
